

An aerial photograph of Lake Shasta, a large reservoir in California, surrounded by rugged, forested mountains. The lake's dark blue water contrasts with the green and brown slopes. In the distance, a snow-capped mountain peak is visible under a clear sky. The text of the presentation is overlaid on a semi-transparent white box in the center.

# Using Idealized FIRO to Understand the Upper-Limit of Future Projected Storage at Lake Shasta

**M. Sierks<sup>1</sup>, M. Dettinger<sup>1</sup>, W. Chapman<sup>2</sup>, and M. Ralph<sup>1</sup>**

# What Makes Lake Shasta Unique?

Largest Reservoir in California

10% of total built storage

67% of basin is below snowline

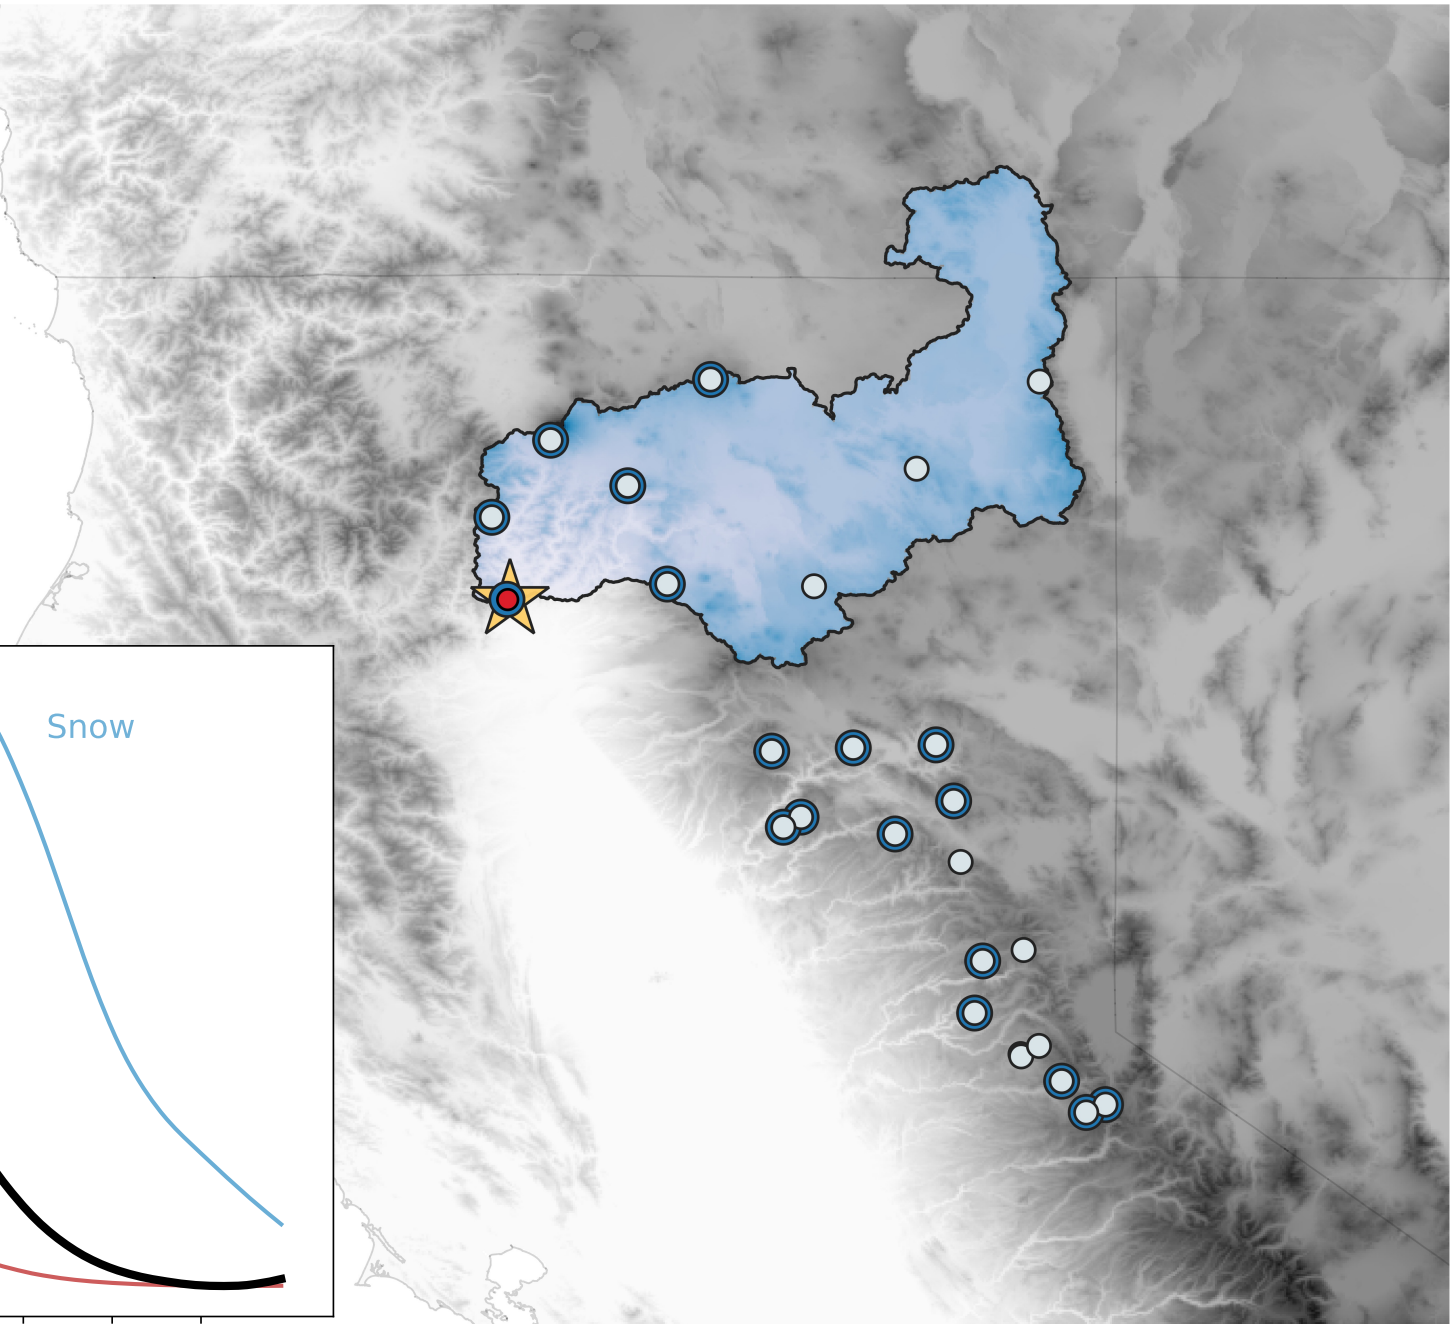

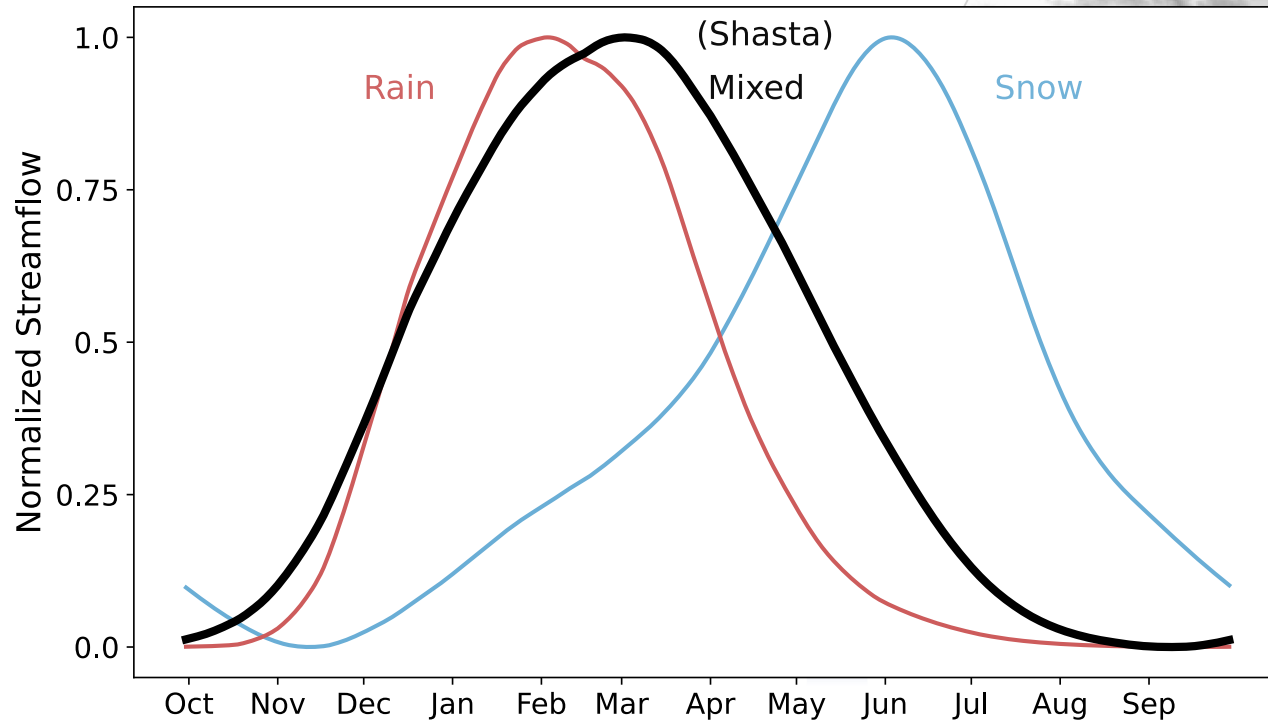

# What Makes Lake Shasta Unique?

Demo: Perfect FIRO

Flood-pool on during wet season

No flood-pool during wet season

RC is dependent on recent inflow  
(that is why the red line is 'jumpy')

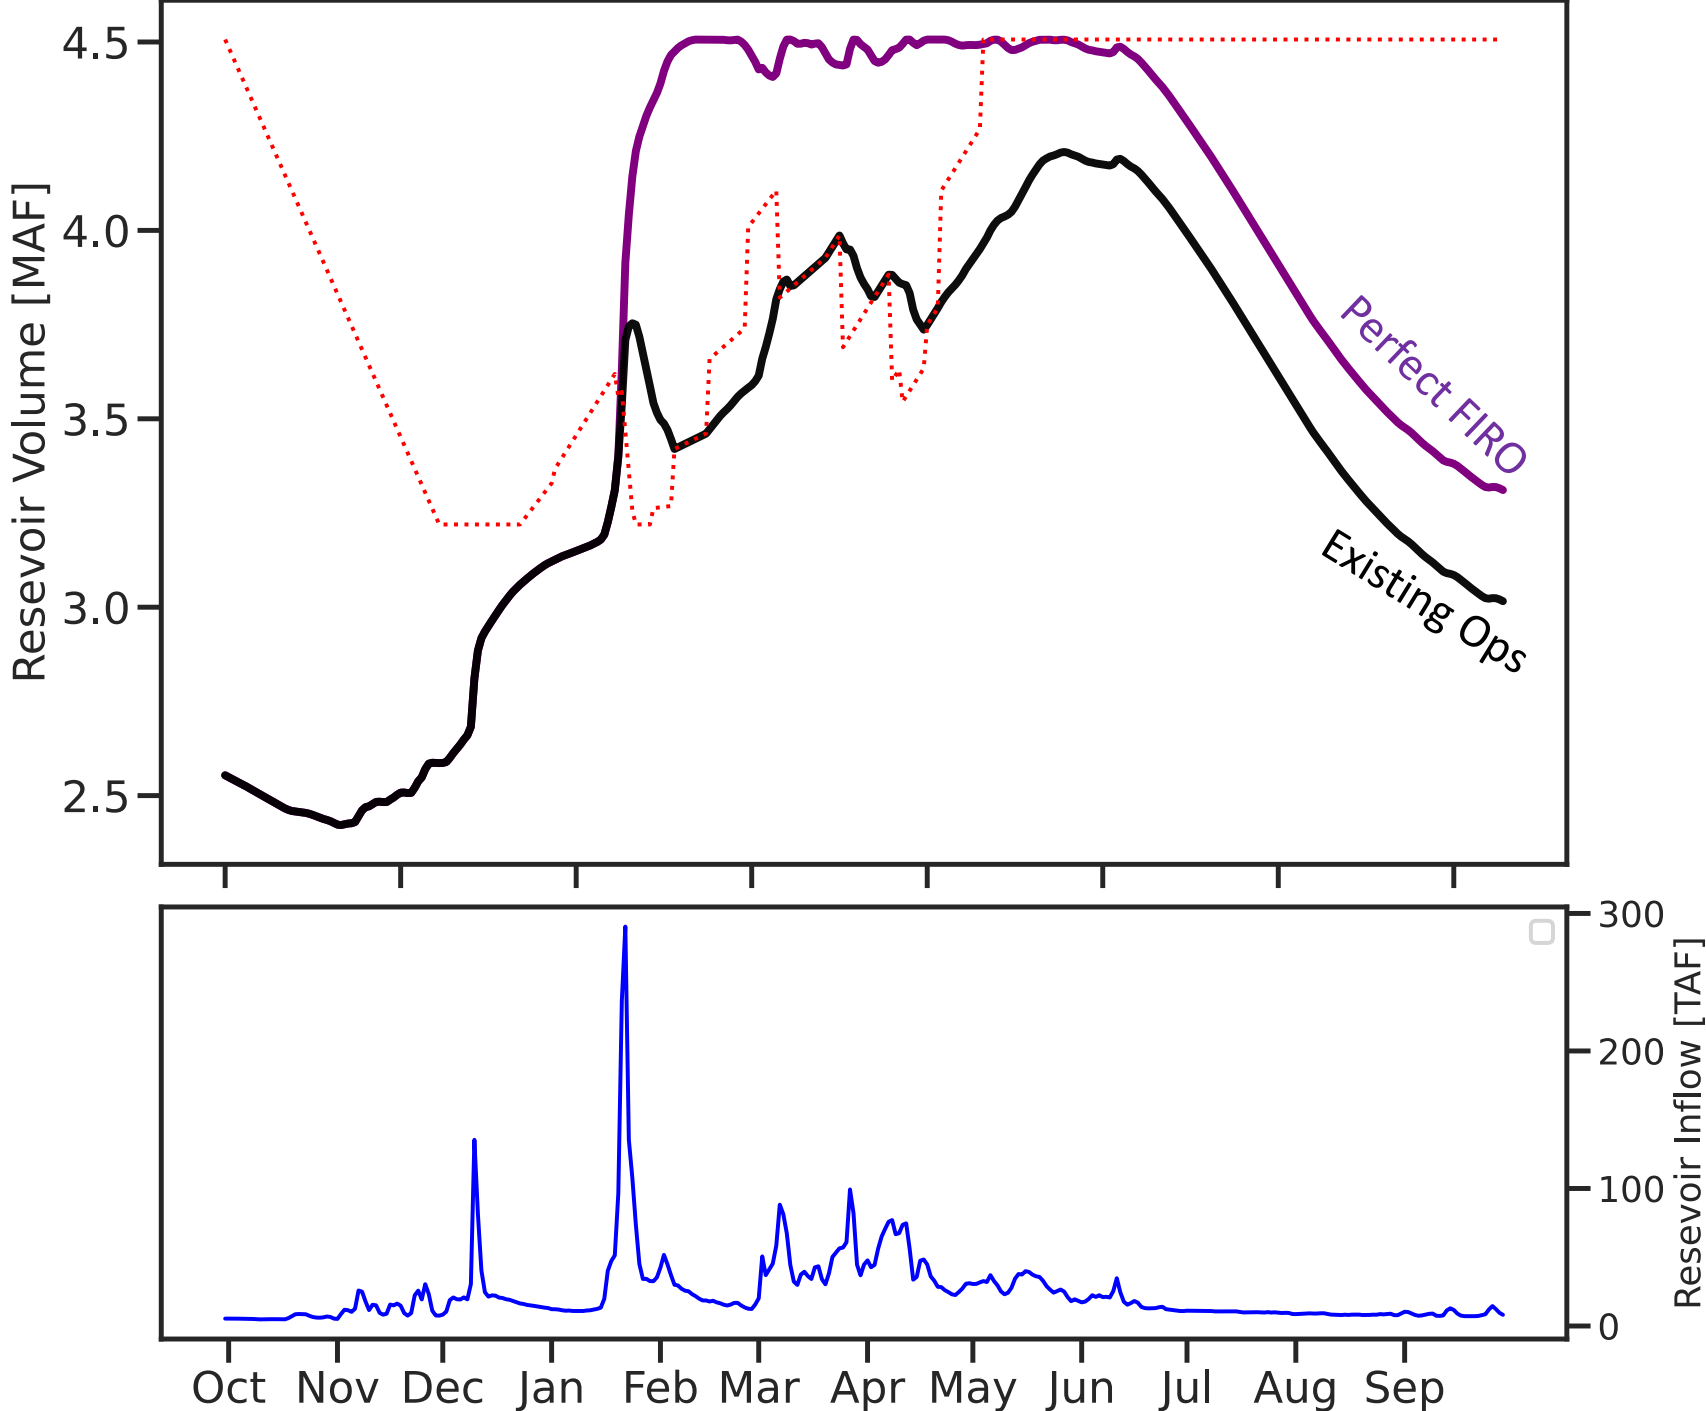

Reservoir allowed to fill ASAP

Flood risk operations respond to  
'water on the ground'

Pre-event releases are made to avoid  
storage exceeding RC

Demand-season May-September

Little change in WY Total Inflow

# Climate Change Projections

Little change in WY Total Inflow

Inflow volume consolidates  
to winter period

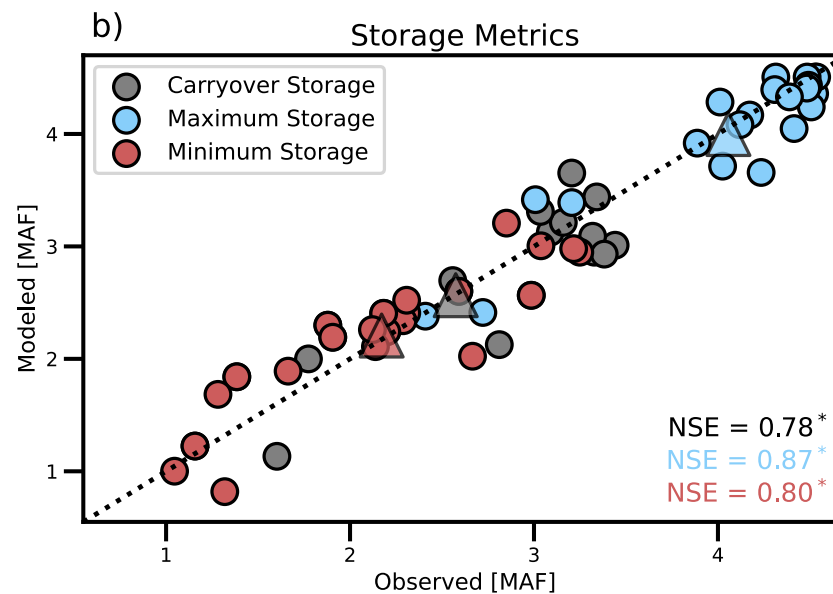

Decrease in post-refill inflow

We build a model using station data from around Sacramento River Basin (precip, SWE, streamflow)

Calibrate and Validate over a historical period (WYs 1996-2017)

It does pretty well!  
(you'll have to take my word for it...)

Many reservoirs  
have a rule curve  
(RC)

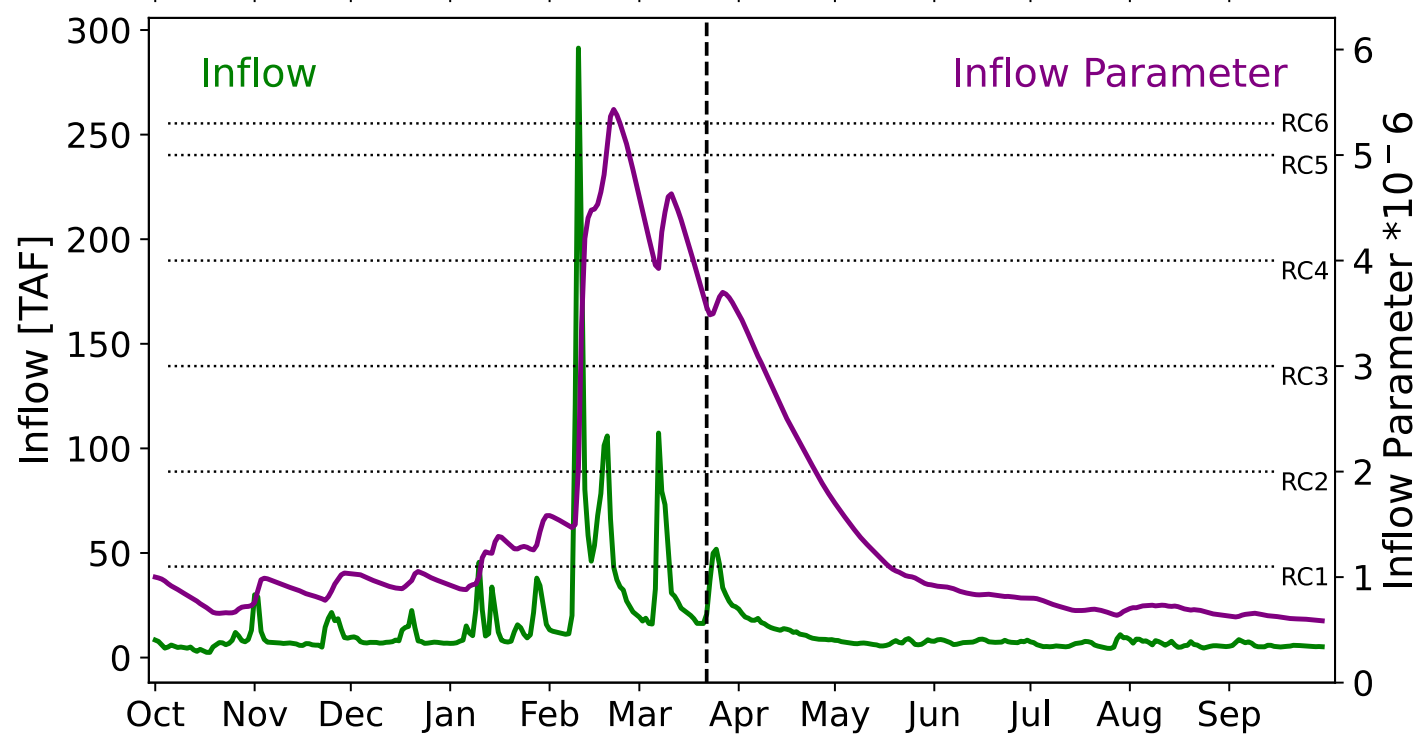

Shasta has 6  
"sub-RCs"  
(blues)

The 'operative'  
value of the RC is  
set by the volume  
of recent inflows  
(red)

**Inflow**  
"Recent Inflow"
